

Hospital pharmacists believe in vaccination. Individuals,

patients, visitors or health workers, who are not vaccinated, can spread infections such as measles or the flu to very ill patients in our hospitals. In addition, vaccination reduces the need for admission to the hospital for us all for preventable illnesses. So to protect very ill patients and to help ourselves stay well hospital pharmacists recommend vaccination wherever possible.

Shortages of preventable medicines ? such as vaccines ? are also a big concern for hospital pharmacists. The results of the 2018 Medicines Shortages Survey of the EAHP showed that preventative medicines (e.g. vaccines) are the second highest reported area of medicines in shortage with 43% of participants reporting them to be an issue. The shortage problem for vaccines considerably worsened in the last couple years since data collected by the Association in 2014 indicated that only 20% of hospital pharmacists participating in the 2014 Medicines Shortages Survey reported them to be a problem.

EAHP consequently calls on the European institutions to address the growing vaccine shortage problem at European level through an investigation into the causes and through the provision of solutions for preventable shortages.
