# A COMPARATIVE LIFE CYCLE ASSESSMENT OF DIFFERENT PACKAGING OPTIONS FOR ALBUMIN DISTRIBUTION

A. Bala Gala<sup>1</sup>, R. Antúnez Retamal<sup>2</sup>, L. Clemente Martí<sup>2</sup>. <sup>1</sup>ESCI-UPF, UNESCO Chair in Life Cycle and Climate Change, Barcelona (Spain) <sup>2</sup>GRUP CARLES, Engineering and Sustainability, Igualada (Spain)

Keywords: ENVIRONMENTAL IMPACT, PACKAGING MATERIAL COMPARISON, LIFE CYCLE ASSESSMENT

## **Background and importance**

**Aim and objectives** 

Figure 1. Lige Cycle stages included

Traditionally, Albumin has been presented in glass vial packaging, but is it the optimal choice for its distributing?

In recent times, many pharmaceutical companies have shifted from glass vials to plastic bags to deliver their hospital products. Plastic bags have demonstrated clear advantages for both nurses (as glass carries a higher risk of breakage) and patients (since the bag does not require air inlet, so there is less risk of contamination). However, plastic bags are often perceived as harmful to ecosystems.

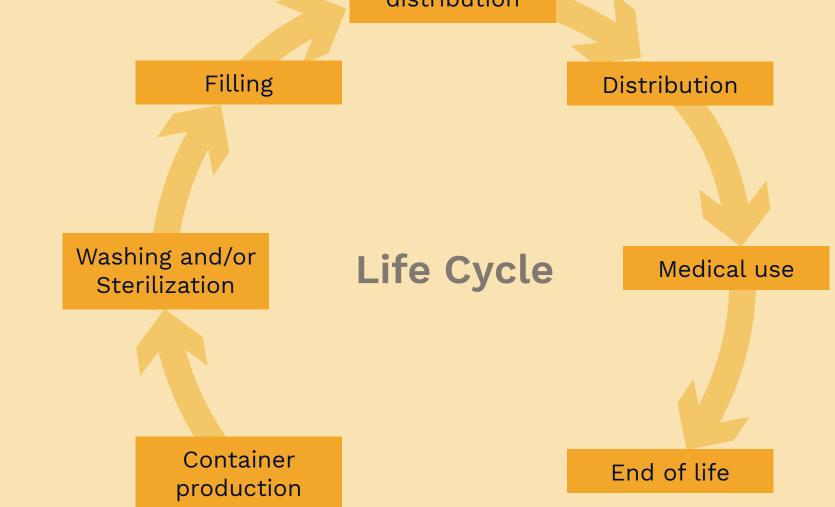

Life Cycle Assessment (LCA) (see figure 1) provides the scientific evidence on the actual impact of the entire process. Therefore, and commissioned by Grifols S.A., this study compares glass and plastic containers for the evidence regarding environmental impacts.

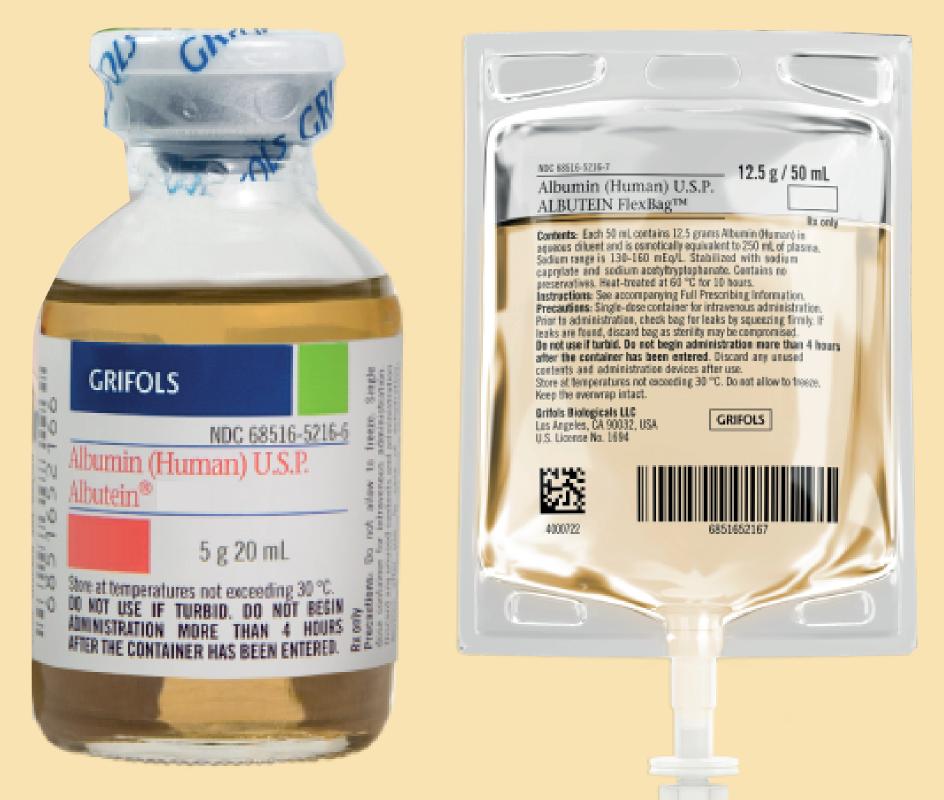

The goal of this study is to compare the environmental performance of glass and plastic packaging options for delivering Albumin 100 ml doses in the <u>European market</u>, considering **all** their life cycle stages.

## **Materials and methods**

A <u>cradle-to-grave</u> LCA has been performed, considering the distribution of **10.000 units** of Albumin (20%) served in 100 ml doses to hospitals as a reference or functional unit.

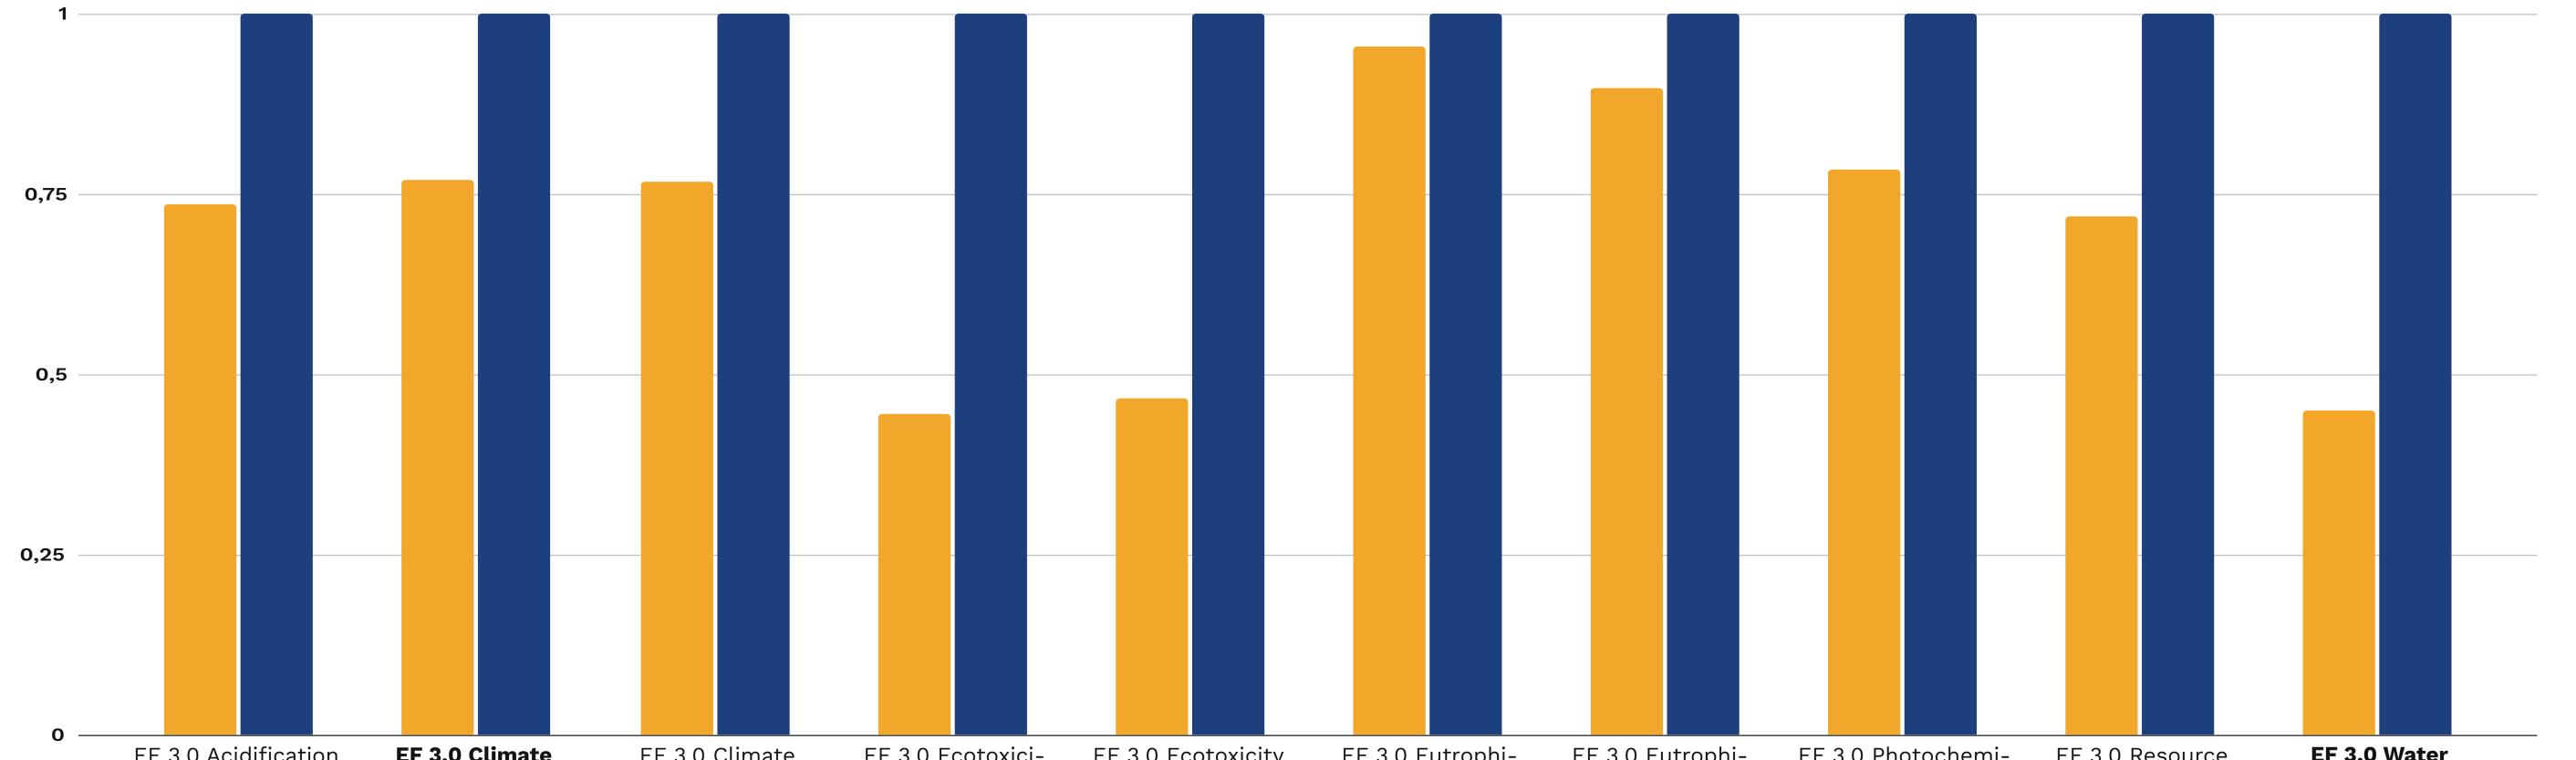

The Product Environmental Footprint method (E.F. 3.0) has been used for the environmental assessment of the alternatives. However, only the more 9 relevant impact categories after normalizing the results plus water scarcity indicator have same product under the LCA metho- been analysed in further detail. The study dology, thereby establishing scientific has been conducted following ISO 14.044 standard, using LCA for Experts software GaBi and their relative databases (2023\_1 update).

### Results

## **Conclusion and relevance**

Plastic bags perform better than glass vials in all the impact categories analysed. Regarding **climate change total** (CC) the improvement is 23%. Also noteworthy is the **55%** reduction in **water** scarcity impact.

Although plastics are popularly considered harmful to ecosystems, plastic bags have less environmental impact than glass vials. So, for 10.000 units of Albumin (20%) served in 100ml dose with plastic bag instead glass vial, the emission of 655 kg of

CO2eq and the consume of 355 m3 of water are avoided. This is equivalent to travelling about 3.930 km in an average car and to take 3.500 five-minute showers, respectively.
