TREATMENT OF THE PREOPERATORY ANEMIA WITH FERRIC CARBOXYMALTOSE

Rodríguez Legazpi I, García Verde MJ, Montero Hernández AM, Rodríguez Penín I
Xerencia de Xestión Integrada de Ferrol. Spain.

Purpose:

To verify the adaptation to a protocol of “PREPARATORY IRON-DEFICIENCY ANEMIA DIAGNOSTIC AND TREATMENT” in patients with programmed presenting moderate/severe hemorrhagic risk surgery (MSHRS), included in a rapid-route surgical program (RRSP). Description of results obtained from the program start-up.

Material and methods:

Retrospective observational study (12/2015-03/2016)

Patients included in RRSP with P-Hb<13 mg/dL going to MSHRS 
Ferritine levels and reticulocyte content determination

If iron deficiency confirmed in Preanesthesia consultation:
- Ferric carboxymaltose (FC): 1 g
- Folic acid: 5 mg orally/day
- Cyanocobalamin: 1 mg subcutaneous/week

If ferritine levels not available, there were rewieved:

</tr>
</tbody>
</table>

Material and methods:

Results:

37 patients initially included in RSSP
Median age: 71 years old (male: 63,66%)

4 patients excluded [admitted (n=2); pending Preanesthesia consultation (n=2)]

18 patients with P-Hb< 13 mg/mL
Median age: 73,4 years old (male: 55,5%)

14 patients received FC, folic acid and cyanocobalamin.
No patients had ferritin levels or CHR

Diagnoses

- Colorrectal cancer (n=27)
- Gastric cancer (n=3)
- Pancreatic cancer (n=1)
- Esophageal cancer (n=1)
- Cholangiocarcinoma (n=1)

Material and methods:

Conclusion:

- In view of the results, the protocol is not being adequately met: inclusion of patients with different diagnoses of MSHRS were included, and no determination of ferritin levels and RHC. This study allows to detect deficiencies in our program to be able to establish improvement measures.

- The small number of patients included does not allow to draw conclusions about preoperative FC administration effectiveness reducing the number of transfusions in this population.
